

RETRACTABLE EAR PROTECTION DEVICE

FIELD OF THE INVENTION

This invention relates to the field of ear protection systems, and in particular, means for stowage of protective ear devices. Further, the invention relates to an encasement for ear protection devices with means for extension and retraction of protective ear devices.

10 BACKGROUND OF THE INVENTION

Prolonged exposure to environments with insalubrious sounds may be detrimental to hearing and may even cause deafness. Earplugs and ear protection devices have been developed to prevent harm to the eardrum and allow individuals to endure extended time in such environments without harm.

One of the first types of well-known protective earplugs in the United States was the "V-51 R". This earplug was developed during World War II in order to provide improved hearing protection to members of the military who were subjected to the concussive sounds of gunfire, explosions, and extremely noisy work environments, such as at airports or aircraft maintenance facilities.

Today earplugs are more commonly used in manufacturing and research environments where workers' ears must be

protected against very loud, acoustically "high" or treble sounds. These sounds are painful to the ear and can permanently damage a person's sense of hearing.

There have been three common ear protection devices developed to seal the ears of people against loud and harmful sounds, which may occur in environments such as a factories, laboratories, airports and during use of certain machinery. One type is a self-sufficient ear protection device with most of the device entering the ear canal, and which holds itself in position by friction between the earplug and the ear canal of the wearer. The second type of ear protection device has no involvement with the ear canal and is characterized by the requirement of an apparatus, such as a headband, to secure the device in place. The device may either fully cover the ear or seal against the inside walls of the ear. The third device comprises a combination of a form of self-sufficient earplugs coupled to an apparatus.

Self-sufficient earplugs are usually constructed of soft resilient material, cylindrical or slightly tapered and larger than the acoustical canal of the ear. By wedging the plugs into the ear canal, the exterior surface of the plugs conforms to the ear canal and the central portion of the plug inhibits the penetration of loud and harmful sounds to the ear canal. Such earplugs can be constructed

by injection molding a foamable material into a die, which forms a foam body with a smooth thin skin on the outside.

The second type of device comprises ear protection devices mounted at opposing ends of a band that extends halfway about the wearer's head. Traditionally, each earplug seals against the walls of the ear, which surround the entrance to the ear canal. Although not as effective in preventing sound, the ear protection device attached to a band may consist of a full ear covering. Many people also object to inserting objects into their ear canal, as with self-sufficient ear protection devices. This device eliminates that concern. However, unlike the ear canal, which is largely cylindrical and more easily sealed against, the walls *surrounding* the entrance to the ear canal are of a more irregular shape. Therefore, it is much more difficult to construct a form fitting apparatus to effectively prevent the sounds from penetrating into the ear canal.

One disadvantage of self-sufficient ear protection devices are the difficulty an individual encounters when attempting to remove them. When workers handle the earplugs by grasping them, they sometimes pinch the outer skin, which causes it to crack and become irritated. Moreover, when such an earplug body is pressed into the ear canal, the skin on the plug body does not uniformly

contract, so wrinkles may be created through which sound can pass to reduce the effectiveness of the earplug.

A drawback with both types of protective ear devices is the proper placement and stowage of the earplugs when not in use. When the noise level is not high, workers often wish to remove the ear protection device from their ears to allow for better hearing of sounds and avoiding the discomfort of earplugs.. Self-sufficient earplugs, however, are usually small and easily misplaced. Band earplugs are cumbersome and arduous to store and carry.

A combination of the self-sufficient and band types of ear protection was introduced to address the issue of where to place the ear protection device when not in use. This type of hybrid ear protection device was designed as self-sufficient, but coupled to an apparatus, such as a helmet or protective glasses. The ear protection devices are usually coupled to the apparatus through cords or bar attachments. The length of these attachments typically is preset and only minor alternations are possible.

This third approach does not, however, provide a secure place to stow the device when it is not in use. Additionally, it is limited because users may find that a helmet or protective glasses are not always necessary. For example, if an individual works in proximity to a loud factory area or in an airport, eye and head protection are

not required, but ear protection would still be advantageous.

An additional disadvantage of the aforementioned ear protection devices is that they are unattractive. If the user perceives the appearance to be unattractive, he or she may choose to refrain from using the protector, leading to unnecessarily increased danger. It would be desirable to design such an apparatus that is inconspicuous or visually pleasing.

SURVEY OF PRIOR ART

In order to provide background information so that the invention may be completely understood and appreciated in its proper context, reference may be made to a number of patents and products:

The "V-51 R" is one example of a self-sufficient type of earplug. The "V-51 R" earplug is composed of a resilient elastomeric material, neoprene rubber, and comprises a single retroverted flange element extending from the nose end of a tubular rubber stalk member. The flange element extends rearwardly from the nose of the tubular rubber stalk. During use, the earplug is forcibly inserted into the ear canal, thereby at least partially collapsing the rearward extending flange element into the underlying free annular space and conforming said flange

element into an acoustic sealing relationship with the constraining walls of the ear canal.

Leight U.S. Pat. No. 3,970,082 teaches of an ear protector assembly mounted to a protective helmet. Leight
5 exemplifies the desire to incorporate a means for stowage in ear protection devices. Leight discloses an ear protection assembly coupled through a linkage to the helmet consisting of pivotal bars allowing for alignment with the ear canal of the wearer. The linkage may move around the
10 rim of the helmet and rest upon the rim for stowage. Although the invention provides a means for stowage, it is a complex, bulky contraption that lacks a visually pleasing façade. Additionally, the requirement of wearing a helmet can be unnecessary and uncomfortable.

15 A self-sufficient ear protection device is described in Falco U.S. Pat. No. 4,867,149, disclosing a solid shaft member to support multiple flanges. The central solid shaft member has the advantage of allowing the earplug to be fully inserted into the ear canal as long as the
20 material is of a sufficient hardness to allow for this full insertion. This type of earplug can create discomfort in the wearer because these self-sufficient earplugs exert excessive pressure on the walls of the ear canal. This earplug disclosed in Falco is also subject to easy
25 misplacement.

Hildenbrand U.S. Pat. 5,231,704 depicts an ear protection device attachable to chin straps of a helmet. The ear device comprises a covering member, which is positioned on or around the chinstraps and in contact with the bottom edge of the helmet. This device provides an attachment means, yet no means for stowage. This device also requires the inconvenient, unattractive and possibly unnecessary action of wearing a helmet.

Carrigan U.S. Pat. No. 5,332,871 discloses an improved efficiency earplug entitled "Sliding Valve Earplug". It includes an earplug body having successive and larger rubber hemispheres mounting a valve body to the ear. The valve body defines an aperture centrally of the plug body and central to the ear canal. A slide acts as an acoustical valve seat and selectively opens and closes the valve body. This slide is linear in motion; its size and excursion is dependent upon the physiology of the ear. It brings a sound-transmitting aperture in the slide into and out of registry to permit sounds to directly reach the ear. While this invention improved the efficiency of earplugs it did not teach anything related to the stowage or encasement of earplugs. As with the aforementioned self-sufficient earplug designs, the problems of discomfort and easy misplacement still persist.

Magidson, et al. U.S. Pat. 5,957,136 teaches of an earplug composed of a polymeric material and the method for manufacturing said earplugs. This design includes a hollow member with an open end and a closed end having a rounded cone shape configuration. There is an additional member extending from the first member with the similar configuration but with a larger diameter. The novel shape of the invention improves the earplug in terms of efficiency, yet it does not address the problems of stowage and encasement. Therefore, Magidson teaches nothing that helps to remedy the discomfort and easy misplacement which are eliminated by the present invention.

H.ang.kansson U.S. Pat. No. 5,988,313 depicts an earplug made of an elastic polymeric material and the method for manufacturing it. The earplug comprises an elongated core and a sealing part connected with the core. The sealing part consists of a softer material. This invention provides a desirable improvement in conformability of earplugs with the ear, but does not mention stowage or encasement means. The design strives to eliminate the discomfort of earplugs, yet only reduces it. It would be desirable to provide an easily accessible means of stowage, such as in the present invention, to further diminish the discomfort of earplugs. Whenever an individual experiences discomfort the earplugs may be

removed and temporarily stowed until the discomfort has
ceased. Further, H.ang.kansson does not address the issue
of easy misplacement.

Fleming U.S. Pat. No. 6,082,855 describes an earplug
5 mounted on an eyeglass temple bar that can fit into the ear
canal. The coupling includes a wire of resilient plastic
that is wound into a tight helix. This invention was
designed to curtail movement of the earplugs, yet does not
eliminate it. The earplugs are located on a tight helix
10 cord and hang freely from the eyeglasses. Thus, in
environments requiring extensive movement, the earplugs
become a nuisance. Further, the plugs cannot be used
without the glasses, and requiring eyeglasses is often
inconvenient, unattractive and unnecessary.

15 Leight, et al. U.S. Pat. No. 6,006,857 discloses an
earplug with an increased ability to block noise. The
earplug comprises a soft shell and an insertion stem
facilitating the removal of the earplug. This invention
does not address the need to inconspicuously stow the
20 earplugs when not in use.

Whatever the merits, features and advantages of the
above-cited references, none provide a comfortable, easily
storable and aesthetically pleasing ear protection device.
For example, providing an effective earplug with
25 convenient, accessible stowage means presents a unique

problem, which is not satisfactorily addressed by any of the prior art. Attempts to achieve this objective by the above and other related prior art have resulted in complex contraptions which are awkward in nature or require
5 additional undesirable and often unnecessary elements, such as a helmet or protective glasses.

What is needed is a more adaptable stowage means for ear protection devices, which can be easily accessible, inconspicuously placed, free of complexity and bulk and
10 focused on ear protection specific to an individual.

SUMMARY OF THE INVENTION

The present invention comprises an apparatus for both ear protection and stowage means. The apparatus embodies a
15 means for coupling an ear protection device, such as an earplug, with the stowage device including a means for extension and retraction. The apparatus further includes a means for attaching the stowage device to any variety of easily accessible entities, such as the front or back
20 collar of a shirt.

The encasement of the apparatus in the present invention comprises an anterior and a posterior member, which are secured together. The members are attached in a means that may be separated when desirable, such as with
25 screws. Thus, an individual may conveniently alter any

interior part of the device. Additionally, the members may be constructed of durable, sturdy plastic for prolonged usage.

Mounted on the exterior of the encasement is a rotatable means for coupling the device to an entity for storage of the encasement. The means can include a clip which may rotate 360 degrees along an axis perpendicular to the encasement. The clip may secure the encasement to an easily accessible object. For example, a clip may be mounted to the exterior of the encasement for attaching the device inconspicuously to the back collar of a shirt. Thus, the ability to attach the encasement to a variety of locations make it easily accessible, lessens the possibility of misplacement and eliminates the unnatural and awkward appearance of the traditional ear protection stowage devices, such as helmets eyeglasses.

The means for coupling each ear protection device to the encasement for the present invention may comprise an extendable and retractable cord. The method of extension and retraction may embody a spool for each cord mounted on a corresponding protruding axis. The axes are secured to the interior of the posterior member of the encasement. A spool rotates in one direction to extend the cord and the reverse to retract the cord.

The spools may incorporate additional features such as a spring-loaded locking mechanism for controlling the extension and retraction of the cord. The locking mechanism may include any of a variety of components, such as a ratchet, pushbutton or thumb slide. Upon extension to a desired length, a locking mechanism may prevent further movement of the spool. Upon release of the locking mechanism, when usage of the earplugs is no longer desired, the spool will rotate in the reverse direction to retract the cord with the corresponding ear protection device to the encasement. For example, the locking mechanism may incorporate a spring-loaded spool favoring the fully retracted position. The cord may be pulled to the desired extended length. A pushbutton may then be pressed to lock the position of the spool and prevent further movement in either direction.

Upon release of the pushbutton, the cord will retract to the encasement providing secure placement of the ear protection device when not in use. A thumb slide functions in a similar manner. To prevent motion of the spool the thumb slide can be moved to one side of a thin slot. Once moved to the opposing side the spool would be released. The length of the cord can vary and may extend to as much as one and a half feet or more.

Furthermore, the present invention may comprise interchangeable self-sufficient ear protection means coupled to the retractable cord. Therefore ear protection means may be changed whenever necessary or desired. For
5 example, it may be desirable to alter or change the earplugs when they have become deformed or when a different individual requests to use the device. Additionally, the device may be used in conjunction with ear protection means in a variety of sizes or types, thus an individual may
10 select their optimum ear protection means. The interchangeable ear protection means may be secured through the use of screws or similar means.

It is an objective of the present invention to provide a durable device for stowage of ear protection means.

15 It is another objective of the present invention to include means for coupling the ear protection device with the encasement.

It is a further objective of the present invention for extendable and retractable coupling means.

20 An additional objective of the present invention is to include a means for attachment of the encasement to an accessible entity.

Still a further objective of the present invention is for the encasement to include a visually pleasing façade.

Another objective of the present invention is to allow interchangeability of various ear protection devices.

BRIEF DESCRIPTION OF FIGURES

5 A further understanding of the present invention can be obtained by reference to a preferred embodiment as set forth in the illustrations of the accompanying drawings. Although the illustrated embodiment is merely exemplary of systems for carrying out the present invention, both the
10 organization and method of operation of the invention, in general, together with further objectives and advantages thereof, may be more easily understood by reference to the drawings and the following description. The drawings are not intended to limit the scope of this invention, but
15 merely to clarify and exemplify the invention.

FIG. 1 depicts an assembly portrayal of the preferred embodiment of the present invention.

FIG. 2 depicts a front perspective portrayal of the interior of the encasement of the preferred embodiment of
20 the present invention.

FIG. 3 depicts a perspective portrayal of the back view of the preferred embodiment of the present invention.

FIG. 3A depicts a perspective portrayal of the side view of the preferred embodiment of the present invention.

FIG. 4 depicts an exploded view of the means for coupling an interchangeable ear protection device to the retractable cord of the preferred embodiment of the present invention.

5

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

As required, a detailed illustrative embodiment of the present invention is disclosed herein. However, techniques, systems and operating structures in accordance with the present invention may be embodied in a wide variety of forms and modes, some of which may be quite different from those in the disclosed embodiment. Consequently, the specific structural and functional details disclosed herein are merely representative, yet in that regard, they are deemed to afford the best embodiment for purposes of disclosure. The following presents a detailed description of several preferred embodiment of the present invention.

FIG. 1 depicts an assembly portrayal 100 of components of the preferred embodiment of the present invention. The assembly 100 comprises a two-member encasement, anterior 101 and posterior 102 with a medial member 104. The anterior 101 and posterior 102 members can be constructed of a durable plastic. The posterior member 102 is a cover for the encasement, which could contain a logo, decal or

other ornamentation to enhance the appearance of the device on the exterior. The anterior member 101 is fixed to the posterior member 102 with screws 103. The encasement may conveniently be uncovered by removing the screws 103. The
5 medial member 104 is securely placed just within the posterior member 102 encasement edges to prevent the movement of the entities within the encasement.

Within the encasement, two axes 105 protrude from the interior of the anterior member 101. Each axis supports a
10 spool 106, wound with a non-elastic cord 107. Each spool 106 rotates in one direction to extend the cord 107 and rotates in the reverse direction to retract the cord 107. Each axis 105 will incorporate a spring-loaded locking mechanism (not shown) to control the extension and
15 retraction of the cord 107. The locking mechanism incorporates a ratchet device that favors the extension direction of the cord 107. The cord 107 may then be freely extended to the desired length. The cord 107 will then remain at the desired length until the unlocking of the
20 ratchet device, possibly by slightly pulling the cord 107 in a certain direction. The cord 107 will then be free to retract to the encasement providing secure placement for an ear protection device.

The opposing end of each non-elastic cord 107 is
25 coupled to ear protection devices 108. The ear protection

devices 108 may comprise efficient self-sufficient earplugs constructed of a resilient material. With the attachment to the cord 107, the earplugs 108 may be freely extended and retracted. Additionally, the earplugs 108 may be easily removed from an individual's ear by simply pulling on the cord 107, eliminating the cracking of the skin that results from the use of other self-sufficient earplugs. Upon full retraction of the cord 107 the earplugs 108 are securely stowed against the encasement.

FIG. 2 depicts a front perspective portrayal of an embodiment of the present invention without the covering of the anterior member 200. Within the posterior member 101, the two axes 105 are located horizontally adjacent to each other and at the vertical center of the encasement 200. A spool 106 is mounted to each axis 105 wound with a non-elastic cord 107.

FIG. 3 depicts a back perspective portrayal and FIG 3A depicts a side perspective of the preferred embodiment of the present invention 300. The invention 300 incorporates a means for coupling the encasement to an easily accessible entity. The means for coupling is mounted to the exterior of the anterior member 101 of the encasement. The means for coupling comprises a clip 302 possibly constructed of the same material as the encasement members. The clip 302 incorporates a helical spring 303 providing means for the

lower section 304 of the clip 302 to withdraw from the encasement when pressure is applied to the upper portion 305 of the clip 302. The clip 302, while open, may be placed adjacent to the desired entity to be attached. When
5 the pressure is released on the upper section 304 then the lower section 305 closes securing the encasement to the desired entity. The clip may rotate 360 degrees along an axis perpendicular to the encasement. Additionally, visibly in the side perspective portrayal, the screw 103 secures
10 the anterior 101 and posterior 102 members together.

FIG. 4 depicts an exploded isometric view of the coupling of an ear protection device 108 and end of the non-elastic cord 107. The present invention was designed to include interchangeability of the ear protection device
15 108. The interior of the ear protection device 108 comprises a threaded cavity 401. Any size or type of ear protection device with a threaded cavity 401 of the corresponding diameter of the screw 402 may be coupled onto the cord. Thus, an individual may select the protective
20 ear device that provides maximum efficiency and minimal discomfort.

While the present invention has been described with reference to one or more preferred embodiments, which embodiments have been set forth in considerable detail for
25 the purposes of making a complete disclosure of the

invention, such embodiments are merely exemplary and are not intended to be limiting or represent an exhaustive enumeration of all aspects of the invention. Further, it will be apparent to those of skill in the art that numerous changes may be made in such details without departing from the spirit and the principles of the invention.
